ABSTRACT

This thesis presents an attempt to determine fatigue life of reinforced concrete bridges by adopting a non-linear damage accumulation method subjected to different amplitude loading due to passing of vehicles in Nepal. The bridge was modeled in finite element software and static analysis was carried out to determine the stresses acting on a bridge deck. The corresponding stresses in reinforcement bars is determined using limit state method and the stresses are incorporated in sequential law to carry out the fatigue life. Since S-N curves available in different codes represents stresses corresponding to more than hundred thousand cycles of failure, a full range S-N curve is developed to carry out sequential law. The material properties of the modeled bridges are taken from design data. The thesis concludes that the fatigue damage due to sequential law is low in previous years; however, there is exponential increase in damage in later years. Although the updated linear method seems to yield almost comparable result as sequential law, the fatigue progress is best represented by sequential law. In addition, the fatigue life for various overloading conditions is determined, and change in damage for respective overloading is analyzed.

ACKNOWLEDGEMENTS

I wish to express my sincere gratitude to my supervisor and our program coordinator Prof. Dr. Kamal Bahadur Thapa, for his continuous guidance, inspiration and encouragement during the thesis work and study period. His lectures and advices proved to be valuable in process of this thesis work.

I would also like to acknowledge all the faculty members of Department of Civil Engineering for the knowledge and concepts they gave me during my study at IOE, Pulchowk Campus.

I am thankful to Roads Board Nepal for providing financial supports to conduct this work. Also, I am thankful to Center for Infrastructure and Development Studies (CIDS) for providing support and knowledge for completion of this study.

I would like to express my sincere gratitude to Asso.Prof Dr Jagat Kumar Shrestha and Ass.Prof Dr Rojee Pradhananga for their invaluable support for completion of this study

I would like to express my very great appreciation to Er. Pradeep Tamang, Er. Nishan Thapa, Er. Pramod Tiwari, Er. Bijay Ban, Er. Nishan Pokhrel and my classmates for their direct and indirect help over the period of master's study as well as this thesis.

I would like to recognize the assistance obtained through the reference books and research papers and would like to thank their authors.

To my family, thank you for encouraging me in all of my dreams and inspiring me during the thesis work.

Prabin Wagle

CHAPTER ONE: INTRODUCTION

1.1 Introduction

Transportation infrastructure such as bridges is subjected to repeated cyclic loads throughout their lives that cause fatigue in its structural components. Fatigue, as defined, is the progressive and localized structural damage that occurs due to repeated cyclic loading. Due to continuous repetition of loads fatigue distress occurs and materials like steel undergo brittle failure much before their yield strength is reached. Thus, the nature of loading in bridges can be taken as the major indicator of its performance in fatigue.

In reinforced concrete bridges, deck slabs, which are found to be the most fatigue critical elements for fatigue failure, undergo millions of large load cycles during its service life (Schläfli & Brühwiler, 1998). Deng, Yan, & Nie, (2018) documented a significant reduction in fatigue life of bridge deck considering the coupled corrosion overloading effects. Despite these facts, the prevailing design codes do not consider the effect of fatigue in the design of RC bridge deck slabs. Therefore, research needs to be carried out to determine the service life of RC bridge decks considering overloading condition and fatigue environment.

Different vehicle with different axle weights has different stress impacts on the bridge. The load acting on a bridge is variable in nature. Different vehicle with different axle weights has different stress impacts on the bridge. There have been many studies related to the interaction of lower and higher stress levels in fatigue life estimation. Linear damage accumulation rule recommended by most of the design codes may overestimate or under estimate fatigue damage in the bridge because it does not consider the loading sequence effect. The fatigue performance of the bridges is different than what Miner's rule estimates. In order to incorporate the load sequence effect, a new damage indicator based sequential law as proposed by Mesmacque, Garcia, Amrouche, & Gonzalez,(2004) is useful to estimate the fatigue life of the RCC bridge.

The repeated cyclic loading being the major factor for fatigue, other external factors also accelerate fatigue phenomena. The rapid increment in traffic density and the existence of overload phenomenon amplifies the stress range in the RCC Bridge deck which obviously cause bridge deck to run a higher risk of fatigue damage. The actual truck loading is far more than it is designed for. The bridges are designed for serviceability with a certain factor of safety for loading however for fatigue evaluation,

the overloading of vehicles is not considered. Hence, it is important to consider overloading effects on fatigue life evaluation of the bridge.

Different researches have been carried out for years to have the proper assessment of the estimation of fatigue life of bridges under various circumstances. Stress controlled method, strain-controlled method, and crack propagation method is generally used to assess the fatigue life of various components of bridges. Strain controlled method is considered to be more accurate for low cycle fatigue however bridges are subjected to high cycle fatigue. So, the stress-controlled method is adopted to have fatigue assessment for bridges. Crack propagation method using fracture mechanics seems to provide accurate results but for this, the crack should be monitored from the time when it initiates and it is quite difficult to carry out this process in those bridges that had been built a long time ago. So, in this research, stress monitored fatigue life assessment is adopted.

1.2 Problem Statement/Motivation

The reinforced concrete T-girders comprises almost 50% of bridges built in Nepal. Since the load cycles over the service life is increasing drastically each year, there is a potential cause of structural short service life problem. Hence, the concern in fatigue of concrete bridges is increasing. However, there is still no practice of evaluating fatigue during design of bridges due to complexity in understanding fatigue influence in RCC bridge.

In recent years, various tests on fatigue-induced failure modes have been studied. The influence of fatigue on reinforced concrete is complex phenomenon. (Barnes & Mays, 1999), Yang, Yi, & Li (2017) and Heffernan & Erki (2001) in their different experimental researches concluded the fatigue fracture of tensile reinforcement was dominant factor in governing the failure mode. This result had huge contribution to carry out fatigue life of bridge since the experimental determination of S-N curve was easier for reinforcement bars.

In bridges, damage caused by vehicles of different axle weight is idealized as linear damage of components due to its simplicity in the calculation. So linear damage accumulation theory is used in codes for fatigue life estimation. However, this rule does not incorporate the effect of load sequence. Many types of research have acknowledged the impact of load sequence that arises due to variable amplitude loading. Thus, the

result obtained by this method has questionable inaccuracies. In addition to this, external factors like overloading cause a significant change in stress distribution which are generally neglected during fatigue life estimation.

1.3 Purpose and Objectives of the Study

1. To incorporate load sequence effect using new damage indicator based sequential law
2. To determine the impact of overloading on fatigue performance
3. To estimate the fatigue fracture life of the reinforcement bars in RCC bridge.

1.4 Limitations of study

1. For simplifying the number of cycles per vehicle was assumed equal to one cycle per truck.
2. Concrete cracking was ignored in this study.
3. The effect of overloading was considered only in reinforcement bar.
4. The effect of multiple trucks in bridge was ignored.
5. Local stress effect was ignored in this study.
6. Vehicles are assumed to have permissible designed weight.
7. The effect of dead load on mean stress is ignored.

CHAPTER TWO: LITERATURE REVIEW

2.1 General

Many research articles related to fatigue failure modes, approaches of fatigue life estimation, linear as well as non-linear damage effects and overloading models are studied.

2.2 Fatigue Failure Modes

In a reinforced concrete T-girder bridge, there are basically two failure modes: Concrete failure mode and reinforcement bars failure mode. Various experiments were carried out to find out the dominant fatigue failure mode. Barnes & Mays (1999) conducted fatigue tests on five RC girders and showed the dominant one is fatigue fracture in tensile reinforcements. Heffernan & Erki (2001) in their experimental study on twelve girders found out that the specimens failed as a result of brittle fracture of tensile rebars and they succeeded in increasing fatigue life by using carbon fiber plate (CFRP) due to lowering of stresses in rebars. However, their experimental results were based on small scale specimens. Charalambidi, Rousakis, & Karabinis (2016) studied fatigue behavior of large scale reinforced concrete girders and their test results have shown that the girders, even being large size, primarily failed due to tensile fracture of steel rebars. This concludes that the dominant fatigue failure mode of RC girder is tensile fracture of steel rebars and is irrespective of the size of test specimen.

2.3 Approaches to fatigue life estimation

Distinct academics have recognized different techniques to fatigue life assessment. Using a fracture mechanics method, Arteaga, Bressolette, Chateauneuf, & Silva (2008) and Ma, Guo, Wang, & Zhang (2020) proposed a probabilistic model for fatigue life assessment of bridge girders and beams, respectively. This paper included a variety of materials as well as uncertainty about the surroundings. V, R, & A(2015) used a non-linear finite element and the S-N curve to evaluate the fatigue of an RCC bridge. Field strain measurements were used by Alampalli & Lund(2005) and Zhou(2005) to determine fatigue life. Strain gauges were put in various locations to obtain strain and the accompanying stresses. Many alternative ways are defined, but AASHTO defines the core approach. The S-N curve is commonly used to estimate fatigue life, and many researchers have followed suit, determining the failure number of cycles by locating matching stresses operating on the bridge component.

2.4 Damage models

Bridges must bear fluctuating loads throughout the course of their lives, but because calculating this type of load is difficult, these loads are transformed to comparable constant loads using the rain flow counting method. Damage accumulation is also done using Miner's rule, which is a linear damage accumulation rule. However, Siriwardane, Ohga, Dissanayake, & Taniwaki (2007) and Dattoma, Giancane, Nobile, & Panella (2005) discovered that utilizing Miner's rule for variable amplitude loading, life estimates were shown to be incorrect since it does not account for load sequence effects. As a result, novel damage accumulation algorithms that account for non-linearity and load sequence impact have been devised. For variable amplitude loading, Dattoma, Giancane, Nobile, & Panella (2005) suggested a novel non-linear continuum damage model. By assuming a new value for the damage function in the damage model, the model calculates the fatigue damage caused by cycles below the fatigue limit. Mesmacque, Garcia, Amrouche, and Gonzalez (2004) suggested a new damage indicator-based fatigue sequential law. By providing a new damage parameter, damage-induced tension is carried from one level to the next until the ultimate stress is reached. Another continuous damage model proposed by Li, Chan, & Ko (2001) used accumulated microplastic strain and current damage state to develop a damage model. Thus, the results obtained using the sequence effect are more realistic than the linear damage accumulation rule, according to the above-mentioned new damage models.

2.5 Overloading models

Various works have been done for fatigue life considering uncertainty due to vehicle overloading. Wang, Deng, & Shao (2016) considered both effects of dynamic vehicle loading and overloading trucks in a steel bridge for calculating fatigue life. In his research three important parameters road surface condition, vehicle speed, and gross weight were incorporated and the vehicle model was adopted from the AASHTO code. Aggarwal & Parameswaran (2015) incorporated various overload factors on trucks with a different number of axle and studied the fatigue life deduction whereas Deng, Yan, & Nie (2018) considered coupled corrosion-overloading effect which provided better results but still the load sequence effect was not considered which would have further increased the accuracy.

Most of the research work assumes constant amplitude loading for its fatigue life estimation because of its simplicity in the calculation and neglect the load sequence

effect. This gives rise to considerable inaccuracy in fatigue life. So, summarizing the researches, it can be concluded that they do not provide the most satisfactory results. To incorporate the limitations, my work will assess the fatigue life of bridge subjected to variable amplitude loading where load sequence effect, as well as overloading effect that influences fatigue life significantly, are considered.

Some literature reviews with their respective methodologies are tabulated below:

Table 1. Literature review with respective methodology

Literature Review	Methodology
(Zhongxiang, Tong, Hebdon, & Zhang, 2018)	Crack growth method
(Yang, Yi, & Li, 2017)	A new relation of fatigue range taking some variables from S-N curve and both concrete fatigue and steel fatigue were considered
(Dattoma, Giancane, Nobile, & Panella, 2005)	Non-linear continuum damage mechanics model where differential equation is solved to get the fatigue cycles of failure.
(Adasooriya & Siriwardane , 2014)	Modified S-N curve and sequential law
(Kwon, Frangopol, & Soliman, 2012)	Fracture mechanics approach but stress range were obtained from modified bilinear S-N curve
(Ni, Ye, & Ko, 2010)	Probabilistic method with continuous probabilistic formulation of Miner's rule and strain monitoring data from long term SHM system
(Leitao, Silva, & Andrade, 2012)	S-N curve method using mesh refining techniques in ANSYS
(Deng, Yan, & Nie, 2018)	S-N curve considering coupled corrosion and overloading effect.
(Wang, Deng, & Shao, 2016)	S-N curve method considering road surface interaction and overloading effects.

(V, R, & A, 2015)	S-N curve using SAP 2000 and non linear analysis of element using ANSYS
(Alampalli & Lund, 2005)	Field strain measurement and using AASHTO specification 1990.
(Siriwardane, Ohga, Dissanayake, & Taniwaki, 2007)	New sequential law and updated S-N curve

CHAPTER THREE: METHODOLOGY

A fatigue damage method for evaluating load sequence effect has been proposed. As a suggestion from AASHTO, the S-N curve is used to determine the failure number of cycles. Since AASHTO suggested S-N curve describes stress range corresponding to more than ten thousand failure number of cycles also known as partial S-N curve so a full range S-N curve is developed using Vechet and Kohout curve modeling technique. The methodology includes:

1. An RCC bridge is selected with consultation from supervisor
2. Geometrical and material properties are determined
3. Average vehicular flow and heavy vehicles flow is counted
4. Finite modeling of the bridge is done and vehicular flow simulation is carried out to determine stresses
5. Limit state method is used to determine stress range
6. Equivalent number of failure cycles is determined using updated S-N curve and sequential law
7. For overloading condition, overloading factors is determined from traffic stations and again updated in finite model

Figure 1. Flow chart of methodology

3.1 Non-Linear Damage Indicator

The most common model to indicate fatigue damage is Miner's rule. However, this model does not take into account the loading history as a result of which, for the same loading condition the experimental results are higher than Miner's expectation for increasing loads and lower for decreasing loads.

The new nonlinear damage indicator is associated with cycles to failure of Wohler curve and experimental results were found to be in accordance with this damage indicator-based results. The damage reported from one stress level is transferred to the next level and this goes on until the component ultimately fails.

A flow chart with an algorithm is shown below:

Figure 2. Flow chart for new non-linear damage indicator based sequential law

Suppose a part of component is subjected to certain stress range of σ_i for n_i no of cycles at load level i and N_i is the corresponding failure number of cycles which is obtained from the S-N curve of corresponding component. Hence the residual life at level i can be obtained as $(N_i - n_i)$. A new damage stress $\sigma_{(1)eq}$ is obtained from S-N curve corresponding to failure cycle $(N_i - n_i)$. Here, the damage stress is stress corresponding to remaining life. Now a new damage parameter D_i is introduced, defined as the ratio of increment of damage stress and difference between ultimate and applied stress. The damage indicator is normalized to 1 at failure.

$$D_i = \frac{\sigma_{(1)eq} - \sigma_i}{\sigma_u - \sigma_i} \quad 3.1$$

Where,

$\sigma_{(1)eq}$ = damage stress

σ_i = applied stress

σ_u = ultimate stress of material

At first cycle, $\sigma_{edi} = \sigma_i$ hence $D_i = 0$ and as no of stress cycles increases, the damage approaches to 1. The damage is then transferred to next level $i+1$ by following relation

$$D_1 = D'_i = \frac{\sigma_{(1)eq} - \sigma_i}{\sigma_u - \sigma_i} = \frac{\sigma'_{(1)eq} - \sigma_{(i+1)}}{\sigma_u - \sigma_{(i+1)}} \quad 3.2$$

Where

$\sigma'_{(1)eq}$ = damage equivalent stress at level $i+1$

σ_{i+1} = applied stress at level $i+1$

We then calculate $\sigma'_{(1)eq}$ and corresponding failure of cycle $N'_{(1)R}$ at level $i+1$

Now for next step applied stress range of σ_2 , and corresponding applied number of cycles n_2 , residual cycles of failure is determined as

$$N_{2R} = N'_{(1)R} - n_2 \quad 3.3$$

With N_{2R} new damage stress $\sigma_{(2)eq}$ is determined and damage is again determined as

$$D_2 = \frac{\sigma_{(2)eq} - \sigma_2}{\sigma_u - \sigma_2} \quad 3.4$$

In the same way the damage is again transferred to next step and same process is carried out until damage is equal to unity.

3.2 Kohout and Vechet Model

In the case of sequential law, it is essential to use full range number of cycles in S-N curve. So the partially known S-N curve is to be developed in full range S-N curve using Kohout and Vechet modelling technique. The procedures are explained below:

Initially, the available partially known curve has to be drawn in the log-log plot. Then draw the three important straight lines:

Line 1: Asymptote $\sigma = \sigma_u$ for the low cycle region (horizontal line across the ultimate strength)

Line 2: Asymptote $\sigma = \sigma_\infty$ for the high cycle region (horizontal line across the fatigue strength)

Line 3: Tangent for the region of finite life described by the equation of partially known curve.

The points of intersection of the tangent (Line 3) with the asymptotes (Line 1 and 2, respectively) occur for $N=B$ and $N=C$. Hence, the equation of fully known curve can be written as the form of:

$$\sigma = \sigma_\infty \left(\frac{N+B}{N+C} \right)^b$$

where b is the slope of tangent in the region of finite life.

Figure 3: Graphical representation of full range S-N curve using Kohout and Vechet curve modelling technique.

3.3 Stress Range

From finite element method, stress in top compression fiber of concrete is determined which is then used to determine the stress in bars. Considering the equilibrium of internal forces on the failure plane, the maximum moments caused by cyclic loading in the normal section of concrete bridge deck can be determined by:

$$M_{max}^f = 1/2(\sigma_c^f * b * x_0 * (h_0 - x_0/3)) \quad 3.5$$

$$b * x_0^2 / 2 - m * A_0 * (h_0 - x_0) = 0 \quad 3.6$$

where

σ_c^f = compressive stress in extreme compression fibre of concrete

b = width of bridge deck considered

x_0 = distance from extreme compression fibre to neutral axis

h_0 = Effective depth of bridge deck

m = ratio of steel elastic modulus to concrete elastic modulus (modular ratio)

The stress range is then calculated using following equations

$$\Delta\sigma(t) = m * (M_{max}^f - M_{min}^f) * (h_0 - x_0) / I^f(t) \quad 3.7$$

$$I^f(t) = b * x_0^3 / 3 + m * A_0 * (h_0 - x_0)^2 \quad 3.8$$

$$b * x_0^2 / 2 - m * A_0 * (h_0 - x_0) = 0 \quad 3.9$$

where

$M_{\max}^f$ = upper limit of fatigue moments

$M_{\min}^f$ = lower limit of fatigue moments

A_o = Cross sectional area of reinforcement bars

3.4 S-N curve

The S-N curve of reinforcement bars has been derived from experimental study by Swiss Society of Engineers and Architects (SSEA) in which they proposed an empirical relationship between fatigue stress and number of stress cycles (SSEA, 1997). The relationship is given as

$$\Delta\sigma = \left(\frac{A}{N}\right)^{1/k} \quad 3.10$$

Where,

$\Delta\sigma$ = stress range

A = fatigue detail coefficient of steel bar

N= no of fatigue stress cycles

K = constant value of the slope of the S-N line

Figure 4 S-N curve of reinforcement bar

CHAPTER FOUR: CASE STUDY

4.1 Structural description

4.1.1 Bridge Model

Bridge Type: Reinforced Concrete Tee Girder Bridge

No of lanes: 2

Total width = 7.5m

Carriage way = 6m (3m each)

Depth of deck = 200 mm

Type of support = Simply supported continuous bridge

Figure 5: Bridge deck section

4.1.2 Superstructure properties

The super structure consists of three longitudinal girders of rectangular cross section of dimension 2000*350 mm. On each span there are seven cross girders of dimension 1500*250 mm joining longitudinal girders at equal interval of 5m. Thickness of deck slab is 200 mm. The grade of concrete used is M25.

4.1.3 Pier and Cap beam

The bridge consists of two single piers of circular cross section and height of 7.87m including cap beam. The cap beam is rectangular cross section of 2400mm * 1400mm and length of 5900mm. The grade of concrete used is M25.

4.1.4 Abutment

The abutment is of rectangular cross section of dimension 7200 mm*1400mm. The grade of concrete used is M25.

4.2 Finite Element Modelling

The basic objective of finite element modeling is to provide the simplest mathematical formulation of the true bridge behavior. Creating a computer model with finite number of members and finite number of nodal displacements that will represent the behavior of real structure is most critical phase. Several commercial finite element programs are available in the market. CSI Bridge 22 is used in this thesis for modeling the bridge and global finite element model of the standard bridge is shown in the figure.

Figure 6 Global Finite Element Model of Bridge

The FE method is highly useful for analyzing problem of complex geometry, materials and boundary conditions. If used properly, we can get reliable result and is cheaper than the experimental testing and analysis. Hence an accurate model is necessary to simulate the actual global structure and accomplish successful analysis.

The Finite Element Method is extensively used in this research to study the stress behavior of RCC T-Girder Bridge. In this study CSI Bridge 22 software is used. Due to its user-friendly interface, the stresses, strains and displacements can be visualized graphically.

In this thesis, multi-step static analysis is carried out. The location of vehicular loading changes and stresses at different loading location is determined to find out the maximum stress at bridge deck.

4.2.1 Material Modeling

Material properties used for the concrete and steel in the Finite Element Analysis are taken from the designed data. The average compressive strength of concrete (f_{ck}) is taken as 25 Mpa. For concrete, a Poisson's ratio of 0.2 was assumed and modulus of elasticity of concrete is calculated as per IS 456-2000 i.e. $5000\sqrt{f_{ck}}$. The unit weight of concrete is taken as 25 KN/m³. The yield strength of reinforcement bars is taken as 415Mpa and ultimate strength is taken as 485Mpa. The modulus of elasticity of reinforcement steel is 200,000 Mpa and Poisson's ratio is taken as 0.3. The mass density of steel is 7850kg/m³.

4.2.2 Boundary Conditions

The bridge is analyzed as simply supported bridge. At abutments, the nodal translations are restrained along vertical axis and the axis which is normal to layout line in the same horizontal plane. At bents, the nodal translations are restrained along vertical axis, along layout line and the axis normal to layout line. Moments are released in all direction in abutments as well as bents.

4.2.3 Geometric Modeling

CSI Bridge 22 is used to carry out the Finite Element Analysis. The bridge deck is modelled by using thin shell elements. The cap bents are modelled by using beam elements whereas the pier and abutment is modelled by using column elements.

4.2.4 Loadings

Different vehicles of respective sizes and axle loads are applied in the finite element software. Point load is assumed for vehicles as local effect due to tyre size is not considered.

Figure 7: Loading diagram for LPK 2518

Figure 8: Loading diagram for LPK 1613

Figure 9: Loading diagram for LPO 1618

4.3 Validation

In this section, the model was verified and is compared with the established result to validate the present model. It was compared with the result of (Pokhrel, 2013). The comparison are as follows:

Figure 10: Bending Moment Diagram for LL(Envelope)

Figure 11: Shear Force Diagram for LL (Envelope)

Table 2: Comparison Table

	Results from Pokhrel	Current Results	Percentage Error
Live Load Bending Moment (IRC Class A)	1592.25 kNm	1619.5647 kNm	1.715%
Live Load Shear Force (IRC Class A)	294 kN	282.95 kN	3.75%

4.4 Vehicles

Annual Average daily traffic = 26733 pcu

Average no of multi axle trucks = 1387

Average no of double axle truck = 2595

Average no of buses = 1205

Average yearly increment of vehicles = 3%

The types of vehicles used for study are tabulated below:

Table 3 Vehicle details

Vehicle Type	Bus (BS)	2AT	MAT
Vehicle Name	LPO1618	LPK1613	LPK2518
Wheel base	6.3 m	3.58 m	3.88 & 4.88 m
Total length of vehicle	12 m	6.365 m	7.08 m
Width of vehicle	2.6 m	2.115 m	2.44 m
Max permissible FAW	54 KN	60 KN	60 KN
Max permissible RAW	108 KN	102 KN	190 KN

CHAPTER FIVE: RESULTS AND DISCUSSIONS

5.1 S-N curve

From experimental study by Swiss Society of Engineers and Architects (SSEA) in which they proposed an empirical relationship between fatigue stress and number of stress cycles (SSEA, 1997). The relationship is given as

$$\Delta\sigma = \left(\frac{A}{N}\right)^{1/k}$$

It has been experimentally verified that the slope of the S-N curve changes at 5×10^6 failure number of cycles. The experimental curve is given in figure 4.

Stress and their corresponding failure number of cycles of reinforcing bars are tabulated below:

Table 4 S-N curve data for reinforcing bars

Stress(Mpa)	Failure no of cycles
359.48	1.00E+05
302.29	2.00E+05
254.19	4.00E+05
229.69	6.00E+05
213.75	8.00E+05
202.15	1.00E+06
169.99	2.00E+06
142.94	4.00E+06
135.19	5.00E+06
128.68	7.00E+06
122.29	1.00E+07
104.53	3.00E+07
97.17	5.00E+07
92.61	7.00E+07
88.01	1.00E+08

For the development of full range S-N curve the kohout and vechet modeling yields equation which is expressed below:

The equation of stress and failure no of cycles for full range S-N curve is developed as

$$\sigma = 63.34 \left(\frac{N + 14259.12}{N + 10^9} \right)^{-0.189} \quad 5.1$$

Where,

σ = stress range

N= failure no of cycles

Table of stress and failure no of cycles after vechet and kohout modelling are presented below:

Table 5 Full range S-N curve data

Stress(Mpa)	Failure no of cycles
580.2899	1.00E+00
580.2592	5.00E+00
580.1055	2.50E+01
579.3412	1.25E+02

5.5 Fatigue damage for overloading cases

The different vehicle model taken for the analysis, in real field, are overloaded to a great extent. The impact of overloading for different overloading condition are carried out and compared.

5.5.1 10% overloading case

The axle load of each vehicle used for the analysis are increased by 10% and stresses are determined. The corresponding stresses in reinforcement bars are determined and are embedded in sequential law to carry out non-linear analysis of fatigue life. The corresponding stresses are shown in Figure 19 and fatigue damage is represented in Figure 20:

Figure 19: Loading condition

5.5.4: Overloading case for Nepal

Department of Transport Management under Ministry of Physical Infrastructure and Transport has carried out a report on axle load control along national highways (Department of Transport Management, 2021). Results of traffic volume and axle load surveys carried out by the DoTM in 2016 along Prithvi Highway (Naubishe/ Dharke Dhading) is taken as representative traffic volume and level of loading in typical road of Nepal.

The result of the survey shows that for heavy trucks (legal load limit= 16.2 ton), average overloading weight is 1.21 ton which is 7.46%. Similarly, for multi axle truck (legal load limit = 25 ton), average overloading weight is 7.44 ton which is 29.46%. These values are incorporated to get the fatigue life of bridge.

Table 15: Damage by sequential law and Miner's rule for overloading case of Nepal

Table 16: Comparison of reduction in fatigue life

Fatigue Life (Years)						
Overloading factors	Sequential Law	% Reduction	Miner's Law	% Reduction	Updated Linear	% reduction
0	113	-	91	-	118	-
10	70	38.05	53	41.76	72	38.98
25	38	66.37	24	73.63	39	66.95
50	15	86.73	7	92.31	15	87.29
Nepal case	40.2	64.42	24	73.63	41.4	64.92

DISCUSSION OF RESULTS

The steepness in graph in damage of sequential law demonstrates that the damage is comparatively very high in later years than the early years. As fracture mechanics explains, for the first few years, the initiation of cracks in rebar does not occur. Once the crack initiates, the propagation of crack is rapid and the damage is exponential and the result shows the same. As stated earlier, the damage by Miner's rule is almost linear. Comparison results shows almost 22 years variation in fatigue life in no overloading condition for sequential law and Miner's law approach. Updated linear method where the damage is ratio of cycles acted to failure number of cycles from updated S-N curve is almost comparable to sequential law approach however, the fatigue progress is best represented by sequential law.

Different overloading conditions shows great variation in fatigue life. Table 16 shows the variation of fatigue life for different overloading conditions. Even 10% overloading condition can decrease fatigue life up to 38%, 25% overloading condition can decrease fatigue life up to 66% and 50% overloading can decrease fatigue life up to 86%. Considering the overloading condition existing in roads of Nepal, it was seen that the fatigue life decreased up to 64%. This shows that even low overloading can cause significant damage to the bridge. However, if there is no overloading condition, the fatigue life is greater than the design life of concrete, and thus problems due to fatigue may not occur.

CHAPTER SIX: CONCLUSION

6.1 Conclusions

In this thesis, the fatigue life of RCC T-Girder bridge is calculated by incorporating the sequential effect which appears due to loading of different amplitudes on bridges. For different vehicles, the stress time history is obtained at bridge deck. The concrete stress is converted to equivalent stress at reinforcement bars using limit state and sequential law is applied to carry out the fatigue damage. The fatigue damage due to Linear Damage Accumulation Rule (Miner's Rule) is also calculated and compared.

From the results obtained, it can be concluded that

1. The fatigue fracture life of reinforcement bars is 113 years by sequential approach and 91 years for linear damage approach.
2. The damage due to sequential law is comparatively low in initial years however there is exponential increase in damage in following few years.
3. The estimated fatigue life using sequential law is high as compared to Miner's damage so the result by linear rule is conservative.
4. Although the updated linear method seems to yield almost comparable result as sequential law, the fatigue progress is best represented by sequential law.
5. For 10%, 25% and 50% overloading conditions, the fatigue life were decreased by 38%, 66% and 86% respectively.
6. For overloading condition of road in Nepal, the overloading condition resulted in 64% decrease in fatigue life of bridge.

6.2 Further Recommendations:

1. It is recommended to consider stress concentration effect which would yield much realistic result of fatigue damage.
2. Experimental data retrieval through strain gauges in bridges would yield better results.

APPENDIX

Sample Calculation

Fatigue Damage Calculation

$$\sigma_u = 485 \text{ Mpa}$$

$$\sigma_1 = 97.79 \text{ Mpa}$$

$$\sigma_2 = 74.26 \text{ Mpa}$$

$$\sigma_3 = 67.41 \text{ Mpa}$$

$$n_1 = 506255$$

$$n_2 = 910675$$

$$n_3 = 439825$$

$$N_1 = 128656496$$

$$N_{1R} = 128150241$$

$$\sigma_{1ed} = 97.858$$

$$D_1 = \frac{\sigma_{1ed} - \sigma_1}{\sigma_u - \sigma_1} = \frac{97.858 - 97.79}{485 - 97.79} = 0.000176$$

$$D'_2 = D_1 = 0.000176$$

$$\sigma'_{2ed} = D'_2(\sigma_u - \sigma_2) + \sigma_2 = 74.33$$

$$N'_{2R} = 815708438$$

$$N_{2R} = N'_{2R} - n_2 = 822071636$$

$$\sigma_{2ed} = 74.34$$

$$D_2 = \frac{\sigma_{2ed} - \sigma_2}{\sigma_u - \sigma_2} = \frac{74.34 - 74.26}{485 - 74.26} = 0.000198$$

$$\sigma'_{3ed} = D'_2(\sigma_u - \sigma_3) + \sigma_3 = 67.493$$

$$N'_{3R} = 2675619482$$

$$N_{3R} = N'_{3R} - n_3 = 2736906360$$

$$\sigma_{3ed} = 67.49$$

$$D_3 = \frac{\sigma_{3ed} - \sigma_3}{\sigma_u - \sigma_3} = \frac{67.49 - 67.41}{485 - 67.41} = 0.0002$$

Stress on Rebar Calculation

Width of slab(b) = 1000mm

Location of neutral axis(x_0) = 41.04mm

Effective depth(h_0) = 179mm

Modular ratio(m) = 9

Area of cross section(A_o) = 565 mm²

For LPK 2518 truck

$$\sigma_c = 2.784 \text{ Mpa}$$

$$M_{\max}^f = 1/2(\sigma_c^f * b * x_0 * (h_0 - x_0/3)) = 9444348.058 \text{ N-mm}$$

$$I^f(t) = b * x_0^3 + m * A_o * (h_0 - x_0)^2 = 119906948.3 \text{ mm}^4$$

$$\Delta\sigma(t) = m * (M_{\max}^f - M_{\min}^f) * (h_0 - x_0) / I^f(t) = 97.796 \text{ Mpa}$$

For LPK-1613 truck

$$\sigma_c = 2.114 \text{ Mpa}$$

$$M_{\max}^f = 1/2(\sigma_c^f * b * x_0 * (h_0 - x_0/3)) = 7171462.57 \text{ N-mm}$$

$$I^f(t) = b * x_0^3 + m * A_o * (h_0 - x_0)^2 = 119906949.3 \text{ mm}^4$$

$$\Delta\sigma(t) = m * (M_{\max}^f - M_{\min}^f) * (h_0 - x_0) / I^f(t) = 74.26 \text{ Mpa}$$

For LPO-1618 bus

$$\sigma_c = 1.919 \text{ Mpa}$$

$$M_{\max}^f = 1/2(\sigma_c^f * b * x_0 * (h_0 - x_0/3)) = 6509951.12 \text{ N-mm}$$

$$I^f(t) = b * x_0^3 + m * A_o * (h_0 - x_0)^2 = 119906949.3 \text{ mm}^4$$

$$\Delta\sigma(t) = m * (M_{\max}^f - M_{\min}^f) * (h_0 - x_0) / I^f(t) = 67.41 \text{ Mpa}$$
