ACKNOWLEDGEMENTS

First and foremost, I have to thank my research supervisor, Mr. Bikash Balami. Without his assistance and dedicated involvement in every step throughout the process, this research work would have never been accomplished. I would like to thank you very much for your support and understanding.

I express my warm thanks to everyone who supported me throughout the course of this M.Sc.CSIT research work. I am thankful for their inspiring guidance, invaluable constructive criticism and friendly advice during the research work. I am sincerely grateful to them for sharing their truthful and illuminating views on a number of issues related to the research.

I like to acknowledge CoinDesk datasets and WorldBank database for providing open source dataset used for this experiment.

I express sincere thanks to all the faculty members and staffs of Central Department of Computer Science and Information Technology who helped me in any possible way to complete the work. I cannot remain silent without mentioning Mr. Bishwa Nath Lal Karn who helped me at every aspect of the thesis.

A special thanks goes to Ms. Rakhi Thakur for her words of motivation and support.

ABSTRACT

The increasing popularity of cryptographic currencies, such as Bitcoin, has led to an interest from central banks in the possibility of issuing their own cryptographic currencies. RSCoin is the most noteworthy effort to include banks in Cryptocurrency economy till date. It is a technology developed in initiation of Bank of England in order to introduce central banks in the cryptocurrency ecosystem.

In this work, the RSCoin implementation was extended by introducing Shadow Coins to test the feasibility of the system in respect to the existing payment solutions, which was specified but not implemented in the original proposal. Shadow Coining is a way to incorporate Cryptocurrencies in the Banking system issuing shadow coin in its central ledger for another currency it stores as guarantee. Shadow coins work as the replica of existing coins such as Bitcoin without altering its value enabling the current Cryptocurrency market to thrive as it is also allowing them to be used for day to day use with very small transactions time. Experiments were conducted to study the performance of the central bank and the comparative cost analysis was carried out. The results confirmed the suitability of Shadow Coins as the basis for a centrally banked cryptographic currency model.

Keywords: Cryptocurrency, RSCoin, Central Bank Digital Currency

Chapter 1

INTRODUCTION

1.1 Background

Cryptocurrencies have found considerable success as an alternative trustworthy form of money. Despite a number of advantages over traditional fiat currencies as well as other centrally served digital currencies, there still is a sense of uncertainty on its use as mainstream currency. It is yet to be used as real currency than as commodity or asset. Current cryptocurrencies, starting with Bitcoin, build a decentralized blockchain-based transaction ledger. Such decentralization has benefits, such as independence from national political control, but also significant limitations in terms of computational costs and scalability. [2,3]

The cryptocurrency exchange market is already in the billions of dollars a day and is tripling yearly. At the same time, the number of cryptocurrencies is growing exponentially. There are now close to 1400 cryptocurrencies that come in various flavors. Some of these are ostensibly backed in one form or another and are intended for a variety of purposes. This level of success has caused financial institutions, regulatory bodies and governments to examine the potential impacts of cryptographic currency schemes. The European Central Bank anticipates such schemes are likely to “impact on monetary policy and price stability” whilst concerns have been raised that they are not bound by International Monetary Fund regulation. However, it is also clear that cryptographic currencies offer potential opportunities for financial institutions. Another reason why the popularity of private e-currencies grew so fast was the speculation possibilities it brought with them. Nowadays, most trades in private e-currencies are conducted for speculative reasons and success stories lead to more people engaging in this speculative behavior. The US Federal Reserve has forecasted that they may provide “faster, more secure and more efficient payment systems” whilst the Bank of England has embarked upon an innovation agenda focused on them. It is to be expected that countries and banks will release and maintain their own currencies. [5,25]

Governments are challenged on how to react on the fast growth and rapid expansion of e-currency. The rapid rise of cryptocurrencies has elicited a range of responses from central banks and governments, from trying to co-opt the changes to their advantage to resisting certain developments for fear of stoking monetary and financial instability. [22]

Attempts to bring Cryptocurrencies within the banking fold have been based on the idea of creating an alternate currency to the already existing Cryptocurrency Pool. It is now technologically feasible for a central bank to set up electronic deposit accounts for all of a country's residents, with blockchain technology making it easy for the central bank to manage a multitude of such accounts. [23, 24]

RSCoin was proposed against this backdrop by Danezis and Meiklejohn to address the scalability issues present in existing cryptographic currencies. Bitcoin, for example, has a peak throughput of 7 transactions per second and faces significant challenges in raising this rate. This is in comparison to Visa which can handle a peak of 56,000 transaction per second. RSCoin sets out a cryptographic currency scheme where monetary supply and generation of the transaction ledger is centralized. In RSCoin, the mintettes entity validates and processes transactions before combining them and presenting them to the "central bank" entity to generate the centralized transactional ledger. This negates the need for Proof-of-Work (PoW) computations which are the cause of performance bottlenecks in systems such as Bitcoin. Danezis and Meiklejohn built a test implementation of RSCoin to measure the latency and throughput of transactions from clients to mintettes. [9]

None of these systems, however, had major uptake as a result of credit card transactions becoming the de-facto payment method of internet electronic commerce. Since discarding the already existing Cryptocurrencies altogether to adopt a new one is not possible due to the market value they have acquired, new currency introduced by Central banks will only create a competition with the existing ones. [16, 17]

1.2 Aims and Objectives

This thesis aims in providing a unique solution to current dilemma of introducing centrally banked cryptocurrency by introducing a platform for all possible currencies to coexist. The principle objective of this study is to compare profitability of current currency settlement with the proposed system specifically VISA, MASTERCARD, and Remittance Agencies in terms of a metric ratio.

In particular, the following objectives are considered:

1. To implement Shadow Coin based on RSCoin architecture
2. To analyze the feasibility of this system in terms of profitability, and comparative cost for users and banks with that of VISA MasterCard and remittance

1.3 Scope

Shadow coin uses a unique idea of asset backed currency issued by the central bank for inter-currency transactions. A shadow of a currency coin is issued which can be controlled by bank by its blockchain ledger for the original currency it stores as guarantee. The shadowing information is stored as metadata as the colored coins. This method will make sure the transitioning of Central bank's into Cryptocurrency ecosystem without challenging the existing digital currency market and create a platform for both the parties to coexist. It is based on RSCoin.

In this thesis, a novel concept of using a common platform of Shadow Coin for existing cryptocurrencies is studied along with its feasibility in terms of profit it may generate for the banks so that they will be inclined to pursue such endeavor. In Shadow Coin cryptocurrency framework, central banks maintain complete control over the monetary supply but rely on a distributed set of authorities, or mintettes, to prevent double-spending. It works by keeping the existing coins as leverage/guarantee and issuing a shadow coin of same value to the user whose transactions are controlled by the bank and upon request to bank producing the shadow coin, the original coin is given back.

In this thesis, the viability of such a system is tested for profitability to banks by comparing the profits made by VISA MasterCard as well as International remitters.

1.4 Structure of the Thesis

This report is split into five chapters. Introduction of the thesis along with its objectives and scope are discussed in chapter 1. Previous works related to this thesis is discussed in chapter 2. Theoretical background of the research is introduced and past research undertaken into cryptographic currencies are discussed in this chapter. Research Methodology is discussed in chapter 3. Details of the datasets used and the proposed framework along with the tools used for implementation is discussed and understood in this chapter. Chapter 4 details the result of the experiment in different datasets. Results are also discussed for their correctness and acceptance. The concluding chapter 5 entitled Conclusion concludes the chapter explaining what have been done in the thesis and how it could be used.

Chapter 2

LITERATURE REVIEW

2.1 Background

Cryptocurrencies are a special case of virtual or digital currencies. While digital currencies are defined by their implementation on a computer system, cryptocurrencies additionally use cryptographic functions in the process of authorizing and verifying transactions. In doing so, they are able to dispense with central counterparties while providing non-discriminatory public access and security against fraudulent spending. Cryptocurrencies have gained increasing prominence in recent years. Not only have they become a topic in the mainstream media, but also traditional financial institutions have moved to define their reaction to this new phenomenon. While central banks around the world have set up their own research teams on this topic, traditional financial institutions try to expand their business into this space. [21]

Due to high volatility, Bitcoin and other cryptocurrencies are not generally accepted yet but this may change in the future. So far, strong fluctuations in the purchasing power of cryptocurrencies make it problematic to use them as a medium of exchange for a significant amount of people, because buyers and sellers must foresee, at least in the short term, whether a trade from today is still profitable, cost-covering or loss-making tomorrow. Considering international trade in a global economy, fluctuations as such in the purchasing power of money vary for several kinds of goods and thus are the normal case. Hence, it is a matter of subjective valuation, if and when the fluctuations of cryptocurrencies are acceptable for a substantial number of users to choose it as an exchange media. When the crypto gold rush ends, in which most people buy and sell cryptocurrencies solely to strive for profit, then fluctuations are likely to abate and the actual use case for cryptocurrencies as money may gain momentum – especially if enough people are unsatisfied with the existing monetary regime. [3, 4]

2.2 Existing Developments and Implementations

There have been attempts to simplify the crypto exchange by a number of means. Some Notable Projects are as follows:

2.2.1 FedCoin

FedCoin is a hybrid model where the central bank primarily controls money supply, while it relies on a decentralized set of authorized nodes (Nodes) to verify transactions and prevent double spending. Nodes are commercial banks. Under this regime, the expensive proof-of-work required by a cryptocurrency like Bitcoin can be avoided, while the permissioned ledger will dramatically reduce settlement latency. [19]

Fedcoin begins with a blockchain created by the Federal Reserve, the public monetary authority in control of the production of money and formulation of monetary policy. The Fed would bless this ledger with certain properties: only the Fed would have authority to create and destroy ledger entries, the Fed uses its creation and destruction ability to provide conversion between both its liabilities (the dollar and the Fedcoin) at a ratio of 1 to 1, and all Fedcoin transactions are announced to a decentralized network of nodes for verification making non-Fed nodes responsible for the integrity of the ledger. Should a paper note or reserve entry be destroyed, a Fedcoin would be instantiated, and vice versa. [19]

The goal is to create a stable (less price volatility) and dependable cryptocurrency that delivers the practical advantages of bitcoin even if this means involving the central government and abandoning the Libertarian principles that many believe underlay Bitcoin's creation. [Koning]

Price stability is achieved by tying the value of Fedcoin to the US dollar. Fedcoin would have a fixed one-to-one exchange rate with the US dollar. The Fedcoin proposal involves two-way convertibility, but the Federal Reserve would control both the creation and destruction of Fedcoin. [16]

2.2.2 CadCoin

Project Jasper is an ongoing collaboration between R3 and six private Canadian banks, Payments Canada and the Bank of Canada that began to explore the possibility of clearing and settling large value payments using distributed ledger technology (DLT). Phase one involved a simulation of a

funds transfer that will be implemented in phase two, with the goal to conduct a set of payments between participants using DLT. The simulation begins with participants pledging cash collateral into a special pooled account held by the Bank of Canada. This is done via payments to the Bank of Canada. The Bank of Canada then issues an equal amount of a central bank issued digital asset, referred to in the presentation as CAD-coin, onto the distributed ledger and sends each bank an amount of CAD-coin equal to the amount of cash they pledged. Banks can then send payments of CAD-coin to each other in real time to meet the payment obligations that they have agreed to have settled on this platform and may also send payments back to the Bank of Canada in order to “cash out” and convert CAD-coin back into Canadian dollars. [20]

2.2.3 Digital Trade Coin

Digital trade coins (DTCs) are the asset-backed concept currently under development at MIT. It outlines an approach to building a consortium of sponsors, who contribute real assets, a narrow bank handling financial transactions involving fiat currencies, and an administrator, who issues the corresponding digital token in exchange for fiat payments and makes fiat payments in exchange for digital tokens. In short, distributed ledger technology is applied to give a new lease of life to the old notion of a sound asset-backed currency, and to use this currency as a transactional tool for a large pool of potential users, including small and medium enterprises and individuals. We intend to build a currency, which encourages legitimate commerce, but makes illegal activities difficult. At the moment there is no working prototype for the DTC. [18]

2.2.4 CDBC

Interest in CBDC has been ignited by two unrelated factors—the introduction of Bitcoin and a persistence of negative interest rates in some developed countries.

Currently, there are three approaches to creating CBDC on a large scale:

1. Economic agents, from enterprises to private individuals, can be given accounts with central banks. However, in this case, central banks would have to execute know your customer (KYC) and anti-money laundering (AML) functions, tasks which they are not equipped to perform. Besides, under duress, rational economic agents might abandon their commercial bank accounts and move their funds to central bank accounts, thus massively destabilizing the entire financial system. [21]

2. Inspired by Bitcoin, CBDC can be issued as a token on an unpermissioned distributed ledger, whose integrity is maintained by designated notaries receiving payments for their services. Given that notary efforts do not require mining and hence are significantly cheaper and faster than that of Bitcoin miners, this construct is scalable and can satisfy needs of the whole economy. Users are pseudo-anonymous, since they are represented by their public keys. Since at any moment there is an immutable record showing the balance of every public key, it is possible to de-anonymize transactions by using various inversion techniques applied to their recorded transactions, thus maintaining AML requirements. [8]

3. A central bank can issue numbered and blind signed currency units onto a distributed ledger, whose trust is maintained either by designated notaries or by the bank itself. In this case, it would have to rely on commercial banks, directly or indirectly, for satisfying the KYC/AML requirements. [8, 21]

2.2.5 USC

The CBDC is technically possible but politically complicated. Hence several alternatives have been proposed. One promising venue is USC (Utility Settlement Coin), which is developed by a consortium of banks and a fintech startup called Clearmatics.¹ Initially, USC can be an internal token for a consortium of participating banks. These coins have to be fully collateralized by electronic cash balances of these banks, which are held by the Central Bank itself. Eventually, these coins can be circulated among a larger group of participants. [18]

2.2.6 RSCoin

RSCoin is a cryptocurrency framework in which central banks maintain complete control over the monetary supply, but rely on a distributed set of authorities, or mintettes, to prevent double-spending. While monetary policy is centralized, RSCoin still provides strong transparency and auditability guarantees. There are benefits of a modest degree of centralization, such as the elimination of wasteful hashing. [1]

RSCoin is an alternative approach to solving the scalability issues present within the Bitcoin protocol. The main difference is that it is predicated on a central bank issuing currency rather than currency generated through PoW computations. This allows for the centralization of “generation

of the monetary supply and the constitution of the transaction ledger”. It also removes the need for computationally expensive and wasteful PoW calculations to generate monetary supply and avoid double-spending attacks. There are two logical elements to the design of RSCoin - the mintettes and the central bank. [1, 9]

Mintettes are synonymous with retail banks and it was envisioned that mintettes would be operated by them should the RSCoin framework be introduced to support a centrally banked cryptographic currency. Mintettes “collect transactions from users and collate them into blocks”, similar to other cryptographic currencies. However rather than completing PoW activity each mintette is “simply authorized by the central bank to collect transactions”. [9]

The operational role of the central bank in the RSCoin framework is as follows:

1. Issue currency.
2. Authorize mintettes to process transactions on a per period basis.
3. Receive lower-level blocks, validate them and combine them to generate higher level blocks which seal all committed transactions during a period in a blockchain.

2.3 Approaches Taken by Different Central Banks and Governments

The approaches of governments and central banks to permitting and/or regulating nonofficial cryptocurrencies span a wide spectrum, with individual countries often changing their positions back and forth in response to consumer demand and concerns about financial stability implications. A number of central banks are at various stages of looking into the feasibility and desirability of issuing CBDCs. The status of some key central banks is listed below. [25, 26]

- **In operation:** Tunisia issued the first CBDC, an e-Dinar designed as a virtual account, as early as 2010. It has now been superseded by a blockchain-based centralized digital currency (using the Monetas digital platform) that also functions as a payments system. In 2015, Ecuador introduced a centralized payment system backed by a digital currency but, since the system failed to attract a significant number of users or volume of payments, is deactivating the system in April 2018.
- **Preparation for implementation/groundwork in progress:** China has successfully tested a block-chain based digital notes transaction platform and is developing a digital currency known as the Digital Currency for Electronic Payment. A consortium of Japanese banks plans to introduce a digital currency (J Coin) in time for the 2020 Tokyo Olympics. This project has the approval of the Bank of Japan, which has indicated that it is not considering issuing a digital currency by itself. The Bank of Canada has a joint initiative with the national payment system operator to develop a DLT-based settlement asset for wholesale transactions (Project Jasper). The Monetary Authority of Singapore is developing a tokenized version of the Singapore dollar on an Ethereum-based blockchain (Project Ubin). Senegal intends to issue an electronic version of the eCFA that will co-exist with physical CFA. This will be issued by a regional bank and will not rely on blockchain technology.
- **Evaluating pros and cons, with no specific plans to issue digital currency:** None of the major advanced economy central banks have announced specific plans to issue CBDCs. Some officials of the Bank of Japan, Bank of Canada, Bank of England, European Central Bank, and the Federal Reserve have indicated they are evaluating the pros and cons of CBDCs, although none of them appear to be giving this serious consideration.

- **Active regulation:** Canada and Japan have explicit laws concerning the trading and use of cryptocurrencies. The U.S. considers Bitcoin and other cryptocurrencies as financial assets that are subject to tax laws as well as regulations concerning anti money laundering and combating of financing of terrorism (AML/CFT).
- **Soft/hard bans on cryptocurrencies:** India's central bank, the Reserve Bank of India (RBI), has not provided authorization for any of the institutions it regulates to trade in or conduct business using cryptocurrencies. In April 2018, the RBI prohibited banks, financial institutions, and other regulated entities from dealing in virtual currencies. Korea's regulators have taken a dim view of cryptocurrencies, although they have not banned them outright. China banned domestic Bitcoin exchanges when it was trying to restrict speculative capital outflows in 2017, and has subsequently taken steps to block access to all cryptocurrency exchanges. China has also more recently banned domestic initial coin offerings (ICOs) and prohibited individuals and institutions from participating in them.
- **Passive tolerance:** A majority of countries are in this category, not banning cryptocurrencies but discouraging their use by financial institutions and, in many cases, not clarifying the legal status of such currencies even as means of payment.
- **Governments/central banks issuing their own cryptocurrencies:** Venezuela's government issued the first official cryptocurrency, the petro, in February 2018. In April 2018, Venezuela declared the petro to be legal tender. The petro's value is in principle backed by Venezuela's oil reserves and the cryptocurrency's issuance was intended to bolster public finances and evade financial sanctions imposed against Venezuela by the U.S. and other countries. Russia has indicated that it will issue a CryptoRuble, mainly for the latter reason. Cambodia, Estonia, and the Republic of the Marshall Islands have announced plans to issue official cryptocurrencies.

Chapter 3

Methodology

3.1 Principle

The aim of this experiment is to study how the trend of cryptocurrency operating cost changed through the course of time during past two years when the crypto market was considered extremely volatile and analyze if the shadow coin model is feasible enough under such harsh economic fluctuations.

The idea behind the algorithm is to find the incentive cost of banking system to keep a threshold of digital coin capital in the central banking system. Since central bank cannot force the players in the digital currency market to adopt its blockchain, the only remaining option is to compete with them. So it can act as a trusted intermediary when required.

The methodology applied can be summed up briefly as follows:

1. Take Transaction Volume of n Digital Currencies in the system as Shadow Amount.
2. Distribute the Sum to N number of users in a random fashion.
3. Run Transactions with market-bounds and calculate charges incurred per transaction.
4. Compare the transaction charges with VISA and Master Card Charges

This scope of work was split into three areas:

- Design and build of Shadow Coin model for central bank functionality
- Creating Daily Transaction Sets of each Cryptocurrency
- Making Fee Decisions as per the actual Fee transferred as well as coin generation rewards

3.2 Data Sources

The dataset for this research is taken from open source data available at coinmetrics.io. With dataset were collected for 10 different coins for a time period of 8 Quarters of 2016 and 2017. For the Visa/Master Card, data were produced as per their quarterly profit and charges data available. Merchant fees are taken from publication of reserve bank of Australia. Values for remittance were used to compare inter country currency flow, and were also compared with the different coin's profit because the coin addresses are boundary less.

The real world data mentioned above were taken from following sources:

<https://coinmetrics.io/data-downloads/>

<http://remittanceprices.worldbank.org>

3.3 Dataset

Three different types of dataset have been used in this study. Namely,

1. Cryptocurrency Data of 10 Cryptocurrency Coins
2. Merchant Fees data of Visa and MasterCard
3. Remittance flow Data of inter country money flow

The Major Digital Currencies as per their market Capitalization Selected for transaction:

1. BitCoin
2. Dash
3. DigiByte
4. DogeCoin
5. Ethereum
6. LiteCoin
7. Monero
8. Ripple
9. VertCoin
10. Zcash

3.4 Data Preprocessing

The available data was preprocessed to fit in the requirement of the study by Data Truncation and Data Merge. The charges for every transaction was taken as main reference. The simulation was carried out so as to conciliate the data values in data set. The data was modeled in the timespan of quarters of year so as to make the accurate comparison with Master/Visa and Remittance which are also published with quarterly average. Trade Volume Based Randomization of transactions were done using Normal Distribution keeping number of transactions and total transaction amount equal to the daily transaction values of the coins selected.

Following Considerations were made while quarrying Data:

1. Daily on-chain transaction volume is calculated as the sum of all transaction outputs belonging to the blocks mined on the given day.
2. Transaction count figure doesn't include coinbase and coinbase transactions.
3. Active addresses is the number of unique sending and receiving addresses participating in transactions on the given day. For Monero, an upper bound for this metric (calculated as sum of input and output count) is reported, as the precise value is unknowable due to stealth addresses technology.
4. Payment count for coins is defined as sum of outputs' count minus one for each transaction. It is assumed that transaction with N outputs pays to N – 1 addresses and the last N-th output is change. Transactions with only one output do not contribute to payment count, as they are likely to be a self-churn.
5. Payment count for Ripple is the amount of XRP token transfers. Ripple data includes only transactions of Payment type that transfer XRP tokens.
6. Zcash figures for on-chain volume and transaction count reflect data collected for transparent transactions only. Transaction volume figures in reality are a little higher than the estimate presented here, and NVT and exchange to transaction value lower.
7. Monero transaction volume is impossible to calculate due to RingCT which hides transaction amounts.

3.5 Data Snippet

- Data Snippet for Cryptocurrency

Date	TxVolume	TxCOUNT	Marketcap	Price	ExchangeVolume
01/01/2016	TsVolume 1	TxCOUNT 1	Marketcap 1	Price 1	ExchangeVolume 1
---	---	---	---	---	---
31/12/2017	TxVolume n	TxCOUNT n	Marketcap n	Price n	ExchangeVolume n

- Data Snippet for VISA/Master Card

Date	Payment Module	TxCOUNT	Charges for Credit Cards	Charges for Debit Cards
01/01/2016	VISA/Master Card	TxCOUNT 1	CreditRate 1	DebitRate 1
---	---	---	---	---
31/12/2017	VISA/Master Card	TxCOUNT n	CreditRate n	DebitRate n

3.6 Environments

The Architecture for the simulation of data is referenced upon RSCoin model. The experimental setup of the original paper, was modified for the tests were run on localhost on Intel CORE i5 7th generation Machine with 4 GB RAM Computer because of the minimal resource requirements.

The Simulations were run in Virtual Environment using Python Language. Python 3.6 was used to build and run the model. The choice of development language was based on its ease of use and dynamic compilation. The choice of Python as a development language is well suited to rapid prototyping as a result of the rich repository of add-on modules available under open source licenses that can be used as building blocks to accelerate development. This was particularly relevant for RSCoin where the use of client / server communications and cryptographic primitives was required. Since the goal of the thesis was to extend the existing implementation, this rationale continued to apply.

Since the existing RSCoin artefact already implemented the scalability and security functionality, shadow coining did not require to validate those properties between clients and mintettes. The Network parameters were muted because the objective of the thesis was in different prototype than the RSCoin paper and significant scope of build activity was focused on to meet data processing objectives of this thesis. Hence the network latency and performance overhead were looked over. For Encryption, RSA algorithm was used.

The Data processing suffered a performance delay due to Python's dynamic nature. During the initial run of the experiments, Unexpected Program exits were the caused by fault as a result of exhausting available physical memory. Total Number of rows were in millions. This situation was remedied by using the higher specification. Database corrections were made to use Microsoft Access Database using Microsoft ODBC Driver. The Result set was copied in a spreadsheet and analytics was done using the statistical tools in Excel.

3.7 Model and Algorithm

The RSCoin Model (Appendix 7) has been modified to run in a single node machine. The Changes in the system are as follows:

1. Elimination of Network Mining
2. Normalized Coin Distribution

The message flows in the logical architecture of the Shadow Coin implementation are as follows:

1. Clients execute the PC to confirm a transaction against input and output shard mintettes.
2. The mintettes seal client transactions into lower-level blocks at the end of each epoch and place them onto the queue.
3. The central bank removes lower-level blocks from the queue, validates them and stores them until the end of the period.
4. Mintettes are notified that the current period has ended and that production of lower level blocks should pause.
5. All transactions received by the central bank in lower-level blocks during the period are sealed in the central bank blockchain.
6. Mintettes are notified that the new period has opened and that they should resume generation of lower-level blocks.

3.8 Implementation

The following stages were undertaken in the implementation of the experiments:

- System Design
 1. Active Addresses
 2. Nodes/Mintettes
 3. Network hosting on Local host
 4. Block generation

- Simulation Model
 - ➔ Wallet Generate:
[Generate a 128 bit RSA Private-Public Key Pair]
 - ➔ Transaction Generate: Transaction Addresses and Amounts

Chapter 4

RESULT AND ANALYSIS

4.1 Experiment 1: BitCoin

Average Fee for BitCoin were in the range of 10,000th of decimal in percent. Cost ratio with VISA/MasterCard charges ranged from 2000 in early 2016 to as much as 40,000 in late 2017. Likewise, the cost ratio with remittance charges ranged from 18,000 to 350,000.

Fig. 4.1.1 Bitcoin Fee Variance with Price Fluctuation

Fig. 4.1.2 Comparative Transaction Fees (Percent): BitCoin vs. Master/VISA

Fig. 4.1.3 Ratio of Remittance Charges to BitCoin Fee with Price

4.2 Experiment 2: Dash

Average Fee for Dash were in the range of 100th of decimal in percent. Cost ratio with VISA/MasterCard charges ranged from 1 in early 2016 to as much as 300 in late 2017. Likewise, the cost ratio with remittance charges ranged from 5 to 2500.

Fig. 4.2.1. Dash Fee Variance with Price Fluctuation

Fig. 4.2.2 Comparative Transaction Fees (Percent): Dash vs. Master/VISA

Fig. 4.2.3 Ratio of Remittance Charges to Dash Fee with Price

4.3 Experiment 3: DigiByte

Average Fee for DigiByte were in the range of 100th of decimal in percent. Cost ratio with VISA/MasterCard charges ranged from 5 in early 2016 to as much as 150 in late 2017. Likewise, the cost ratio with remittance charges ranged from 50 to 1500.

Table 4.11.1 Summary of results for the Year 2017

4.12 Result Analysis and Discussion

Following assumptions were made for Fee Calculation of Coin Transactions:

1. The Number of transactions in the banking system is proportionate to that of the real world
2. The Transaction capital in the banking system is proportionate to that of the real world.

Data variations were done in some coins by including the generated coins as well in transaction amount especially at the starting period when the coin generation rates were higher than the transaction amount. The value of generated coins too were taken as charges to adjust the economic benefit value they created for cryptocurrency miners to incentivize the process similarly as the merchant and service fees in the case of debit/credit card providers. The results thus obtained can be summarized in following points:

1. Common Trend

The output of experiment results persisted to display a trend of superior performance of cryptocurrencies in comparisons to the Master/Visa Card. A further reassuring result was the corresponding performance of coins against remittance products.

The results of the experiments 1 and 5 did show a dramatic decrease in fees of as less as ten thousandth part of decimal in percentage, and in the range of tens and hundreds of thousands in card and remittance charge ratios.

Some results did show a slightly less encouraging data, namely experiment 2, 3, 4, 6, and 10, when compared with other experiment results, for example Dash in 2016 had almost the same charges as that of Master/Visa Cards. Whilst this is not a huge performance impact, investigation suggested that the results got better after the price of cryptocurrency stabilized in latter part of 2017.

2. Popular Vs. Beginner Coins

The relation between popularity viz. market capital/transaction volumes with shadow coin performance revealed that more popular coins such as Bitcoin and Ethereum performed exceedingly better than the others.

3. Price Stabilization Effect

The fee percentage of Coins showed a decline in value with each quarter of both the years. This was due to the fact that the fees for coin transactions were made in cryptocurrency coins and as the price of the crypto market stabilized, the crypto to USD ratio became lower with time. Hence, the performance of the shadow coins were also exponentially improved with each quarter.

4. Performance Variants

The market capital and number of transactions per day were found to be the major performance variants for the results. For instance, BitCoin and Ethereum, being the foremost runners in the crypto market performed comparatively better than all other coins. Also, Monero and Ripple showed similar outcomes compared to the remaining coins.

5. Recommendations

It is apparent from the above results that, although the shadow model seems feasible for the Central Banks performance wise, Banks need to outline certain parameters esp. market capital, number of transactions, popularity of the specific cryptocurrency etc. before letting them in its shadow coin blockchain ledger.

In summary, Comparative charges for cryptocurrency were many folds less than VISA/MasterCard and Remittance Charges. Even with price fluctuations, the fees remained a constant low.

Chapter5

Conclusion

5.1 Conclusion

On the basis of the Experimental Results, it is concluded that the proposed shadow coin system indeed provided better incentive for banks to incorporate cryptographic currencies in their economic ecosystem based on performance against Credit/Debit Card Service Providers and Remittance Service Providers. Crucially, there could be one-for-one convertibility with incorporated cryptocurrencies, and hence a retail central bank cryptocurrency would not suffer from the high price volatility that undermines the usefulness of existing cryptocurrencies.

Through the experiments conducted with this extended RSCoin artefact, it was concluded that central bank could benefit from user inducement of reduced charges by a considerable factor. Thus Shadow Coin can be recommended for further consideration by central banks pursuing cryptographic currencies as part of their innovation agendas if other parameters such as network overheads and security performance are made consistent with set benchmarks.

5.2 Future Work

There are a number of areas of interest for future study following on from this work. This can also be used in International trades and cross country transactions. Also, it is assumed that eradicating the proof of work will considerably speedup the transactions and reduce the energy consumption, it is yet to study the exact improvements of the system. Furthermore, Shadow Coining has a prospect of extending its use to international trades and facilitation of money transfers between countries/international corporations across borders.

Appendix 6: MS Access Database Store Snippet

The screenshot displays the Microsoft Access interface. On the left, a pane titled "All Access Objects" shows a list of tables, with "BitCoin2017Q4" selected. The main window shows a data grid for this table. The grid has 12 columns: ID, Field1, Field2, Field3, Field4, Field5, Field6, Field7, Field10, Field8, Field9, and Field11. The data is organized into 25 rows, with the first row (ID 1) highlighted in yellow. The status bar at the bottom indicates "Record: 1 of 49046".
